

Documentation:

Gathering information about the organization of one aqua health - why they were created, what they are aiming for - looked through their website - went through their videos - analysed their app geossip and citizen science application - carefully chose our track by weighing the pros and cons of each and the relevance and feasibility of the solutions we could find for each - idea formation and progression including sprite and icon designs, UI designs, map, user journey - demo video and prototype

Objective	Description	Supporting Image
Gather information about the organization of aqua health	Research was done about Aqua Health: where they originated from, their goals and aims, who their partners are, and a general overview of their website and apps.	
Geossip App	An overview of what the app is about. What does the current UX look like, its current aim and goals. We looked at it from a user and consumer point of view and tried to understand what aspects would make us want to be a repeat user, or cause low interaction.	
Citizen Science Application	We tried to understand the submission process and how a normal user would interact with this app. Once again, we tried to analyse it from a consumer standpoint. We went through the observation submission process and took note of the aspects we thought could cause low interaction and low engagement. We also tried to list the main features that are essential and cannot be removed.	
Select a track	We listed each track with its challenges, problems and the expected build. We then went through it and explained it in our own words to ensure we understood what each track was at its core. Each team member selected a track and proposed ideas. The team went through each idea and a SWOT analysis	

	was done. The track and idea with the best SWOT analysis was chosen.	
Watch the videos and sessions conducted for the hackathon	We watched the videos and tried to write a summary to refer back to when needed to ensure all team objectives and tasks are aligned with hackathon needs.	
Prototype formulation	Once track 5 was selected, the team brainstormed different ideas and concepts. Each idea was weighed out and factors such as feasibility and implementation were considered.	
Idea formation	Quests badges streaks networking eco systems health affects the players ecosystem, sprite	
	Hello what do u think of what im doing below good or no good	
	Doing awesome amazing	

Gather information

Research was done about Aqua Health: where they originated from, their goals and aims, who their partners are, and a general overview of their website and apps.

Information gathered/notes:

One aqua health is a European research and innovation project that connects the health of urban freshwater ecosystems (like streams, rivers, and ponds) with human physical and mental well-being.

They are being funded by the European Union and their framework is built through 14 collaborative partners across 10 European countries

One Aqua Health has two apps and one website which I think they are aiming to improve (one of the tracks for hackathon as well).

Need to sign in to access full website and apps -

<https://www.oneaquahealth.eu/project-solutions/>

Snapshot from document

Geossip App

An overview of what the app is about. What does the current UX look like, its current aim and goals. We looked at it from a user and consumer point of view and tried to understand what aspects would make us want to be a repeat user, or cause low interaction.

App 1 Geossip:

Allows users to access data from other users all around the world

Confusing to navigate

Expert dashboard accessible by everyone

Citizen Science Application

We tried to understand the submission process and how a normal user would interact with this app. Once again, we tried to analyse it from a consumer standpoint. We went through the observation submission process and took note of the aspects we thought could cause low interaction and low engagement. We also tried to list the main features that are essential and cannot be removed.

App 2 Citizen Science:

Allows users to input data and observations

UI confusing

Submission process can be simplified

Terms might need to be defined so the average person can use

Main features to keep:

Questionnaire layout and questions

My submissions

Selecting a track

We listed each track with its challenges, problems and the expected build. We then went through it and explained it in our own words to ensure we understood what each track was at its core. Each team member selected a track and proposed ideas. The team went through each idea and a SWOT analysis was done. The track and idea with the best SWOT analysis was chosen.

By this weekend (sunday) im hoping we will be able to figure our target problem and have a finalised solution.

Just a basic overview of the tracks to make it simpler to compress and understand:

Track 1: Making their user interface more easy to interact with.

Track 2: Turning the data collected by the citizens into information that is easy to understand and act on.

Track 3: Using AI to access the water bodies they want to monitor as in the app but it shouldnt cut off citizen interaction.

Track 4: Making their application more interactive and memorable

Track 5: How to get people to keep contributing to their app

Track 6: Finding a way to predict environmental problems before they worsen using the data. So we will need to be building an algorithm of sorts

Track 7: Combining databases so that the information from different sources can be used together. For example data given by citizens and their ai are on preexisting separate databases but finding a way to combine them together so they can make more sense. Likeeeee joining puzzle pieces. Theyve given like a sandbox thing which we could work on

I think we could combine tracks1!!

In my opinion track 3, 6 and 7 may be a little too technical

But track 1, 2, 4, 5 are very much workable

Open to all and any suggestions

Watch the videos

We watched the videos and tried to write a summary to refer back to when needed to ensure all team objectives and tasks are aligned with hackathon needs.

1. Introducing the OneAquaHealth Project: 12 June 2026

Main objective: Establish the scientific problem and explain what hackathon teams are being asked to address.

Key ideas:

- Urban streams connect environmental health, biodiversity, animal health and human wellbeing.
- Citizen observations can supplement professional environmental monitoring.
- OneAquaHealth combines citizen-generated information, environmental data, AI-assisted analysis and early-warning indicators.
- Solutions should translate data into understandable information or action—not simply collect more data.
- The hackathon encourages human-centred tools that promote long-term stewardship of urban waterways.

Idea progression

After gaining a general understanding of the background of One Aqua Health and the hackathon, we started devising ideas on the initial chosen tracks: Community and Gamification and, Awareness and Story telling.

how about quests and badges and stuff and then when u add data in it turns it into a mini story about how it affects the wildlife or smth similar

we can make it like a "hay day" game where the eco system's health affects the player's farms, fish, maybe factories(?) and plants. but it's all affected by the real life health eco system's actual health

We propose a community-driven, gamified interface for OneAquaHealth that transforms one-time participation into a sustained social habit. Inspired by LinkedIn's networking and challenge features and Snapchat's streak-based engagement, the platform would use community profiles, team challenges, progress dashboards, achievement badges and participation streaks to motivate users, recognize contributions and encourage repeat engagement.

could be a challenge as to how keep it as healthy as possible or as alive as possible and make leaderboards or something

maybe it can have like a sprite of some sort that engages with other players or guides people to parts of the stream that need more attention and maybe its like if you take up a part of stream that needs more attention you get a rarer sprite

Ayisha: Track 4 and 5

I've sort of combined our ideas into a singular flow of how I like to think it could go

After signing in -> make a new observation by choosing a stream -> Choosing a stream gives the user a basic sprite (random). On choosing a part of the stream that isn't observed usually or needs extra attention a rarer sprite is rewarded to user -> On answering the given questions on their app (presented as helping the sprite to gain information or as an investigation undertaken by the user to help the sprite) -> Maintaining a streak rewards user with badges and levels up sprite -> when the sprite levels up new educational information is unlocked as the user gains more experience (the loading screen also can display information) -> Leaderboards for each country/cluster of observation points. Can connect with other sprites of the same stream. Having community challenges as well as small group challenges can also work.

Additional information: The factors affecting the stream can be shown as icons with levels that change according to whichever ones are affecting them more. Badges can be earned for leveling up, connecting with other users, making a specific number of observations in a period of time, fixing problems that are affecting the stream, and observing data for more streams. etc

Strengths

Makes environmental observation fun through sprites, rewards, badges, and levels.

Encourages people to learn about local streams and environmental issues.

Builds community through leaderboards, shared challenges, and connecting users.

Gives users a clear sense of progress and achievement.

Weaknesses

Some users may prefer simple information rather than game features.

Accurate observations may need checking to avoid incorrect data.

Developing sprites, challenges, and location-based features may take time.

.

Opportunities

Could partner with schools, councils, conservation groups, and community projects.

Can expand to more streams, wildlife topics, and locations over time.

Could support real environmental action by highlighting issues needing attention.

Community challenges can encourage more people to take part and share observations.

Threats

Similar learning or environmental apps could compete for users.

Prototype Formulation

Once track 5 was finalised, the team brainstormed different ideas and concepts. Each idea was weighed out and factors such as feasibility and implementation were considered.

Sprite and Icon design

Progressing through the ideation phase, we decided to carefully design sprites and icons with references to aquatic creatures in the streams of the respective site. This was meant to make the user feel more connected to their sprite as it represented the creatures they've seen in their local streams.

ANIMALS NATIVE TO BELGIUM

Icon design for each data submission category:

Mapping out the UI gave us a clearer idea on the user flow and journey. It allowed easy editing of web pages before committing to the design.

User Interface

The next objective in our progress was to design a user interface that best showcased our track related to gamification and community. We designed an interface that incorporated all of our ideas as well as maintained the app's original purpose.

Prototype

Demo Video

In order to create a demo video that highlighted all the main features of our website we designed a presentation. The presentation condenses and summarises all our main ideas into one site.
